SAAKSHI - Workflow and Integration

Gujarat Police Innovation Challenge 2026 · submitted under **Model 1 (compulsory) + Hybrid**

Every diagram below is generated from a committed mermaid source under docs/architecture/, rendered by `npm run docs:render`. They are the same figures used in the High-Level Design, so the two documents cannot disagree. Sources: <https://github.com/thopatevijay/saakshi>

1 · Integration - what SAAKSHI connects to, and what it leaves alone

Department-owned sources stay where they are and are not modified. Every source type reaches the platform through one adapter interface, whatever its vendor or protocol. Government databases are shown dashed because the connectors are **specified with a mock provider, not connected** - there is no live VAHAN, SARTHI, eGujCop, AFIS or NAFIS link in this submission.

2 · Integration - inside one district node

Decode, detect, track, read plates and probe health, all at the edge. Only events cross the WAN - roughly 2 KB per second per camera. Video never leaves the district, which is what makes the backhaul arithmetic work and what makes 26 departments willing to participate.

3 · Workflow - frame to sighting to alert to evidence

The operational loop end to end. Timing is taken from the presentation timestamp, never frame arrival. A watchlist hit is correlated as the read lands - exact first, then a confusion-weighted fuzzy match. The operator's verdict is written to a hash-chained audit log, and the evidence crop is streamed through the API behind a session and a role check, never a public URL.

4 · Integration - statewide deployment

Approximately 33 district nodes feeding a state data centre over mTLS, with a replicated secondary site. The figure that decides this shape: 1.28 Gbps of metadata in place of 160.00 Gbps of video.
